ABSTRACT

Multi-station aggregation hubs – interconnected transport nodes in high-intensity urban areas – significantly influence metropolitan growth, yet systematic research on their regional development impacts remains limited. This study examines London's King's Cross–St Pancras hub redevelopment using spatiotemporal data (1996–2023). Three analytical zones (Core zone, Central Impact Zone and Wider Impact Zone) were established to assess transport networks, functional vitality, and development intensity via GIS and qualitative methods. Findings indicate a 25:11:8 ratio of renewed building areas across zones, with development intensity strongly correlated to hub proximity. The core zone saw significant growth in consumer/service-oriented POIs, evolving into a mixed-use creative hub. Insights are provided for redeveloping similar hubs in high-density cities, particularly China.

ABSTRACT

Urban rail transit multi-site aggregation lots generally satisfy four attributes at the same time:

Transportation - there is a strong transportation connection between the stations;

Distance - within a certain spatial distance;

Function - There is a strong public correlation between the stations and the lot, as well as between the functional elements within the lot;

Space - the spatial elements within the lot have an orderly, clear, detailed and rich organizational order.

Multi-site Aggregate Lot Boundary Identification and Typing

1. Initial screening of multi-site lots based on site density

("distance" factor, nuclear density analysis)

2. Analysis of the morphology of multi-site lot aggregation characteristics

[Transportation (accessibility), density (road network density, intersection density, public space density, population density, building density and height or number of floors), function (functional mix)]

3. Aggregate lot boundary identification

Boundary delineation based on aggregated feature attenuation

Research Methods

2.1 Case: King's Cross, London

2.2 Documentary Data

this included historical records of the area, planning and design proposals from developers and urban designers, relevant planning documents published on the official websites of the Camden and Islington local authorities, progress reports on the King's Cross core zone (2008–2024) published by KCCLP on its official website, and a 2017 construction evaluation report for the core and impact zones by Regeneris Consulting (Regeneris Consulting, 2017). For spatial and statistical data, the study acquired: Ordnance Survey datasets (2007–2023); Built-environment typology maps, building height data, and Points of Interest (POIs); Transport for London (<https://tfl.gov.uk>): Ridership statistics for stations (2007–2017); UK Office for National Statistics (www.ons.gov.uk): Census data (2001, 2011, 2021) at the Output Area (OA) level, with each OA typically covering 40–250 households.

Discussion and Conclusions

- The redevelopment of King's Cross demonstrates that **the aggregation of transport hubs**—through the expansion of rail networks and integration of existing stations—**creates efficient connectivity, driving increased passenger flows and stimulating demand for complementary functions and spatial provisions.**
- **Proximity to the multi-station hub strongly correlates with development intensity.** From 1996 to 2023, 25: 11: 8 of new floor area per hectare was added in the core, central impact, and wider impact zones, respectively.
- It is foreseeable that with continuous advancements in transportation technology, **the reduced demand for ancillary transport infrastructure and increased functional integration will enable sophisticated mixed-use design to unlock greater development potential in urban multi-hub aggregation zones.**
